Killing predators such as wolves, mountain lions and bears to protect livestock may have intuitive appeal, but a review of multiple studies published Friday shows little or no scientific support that it actually reduces livestock losses. In fact, in some cases it even leads to increases in livestock loss, the nonprofit Center for Biological Diversity stated in a news release.

These conclusions directly counter the reasoning behind the common practice of killing predators in response to livestock depredations, as carried out by the federal Wildlife Services.

"This study shows that not only is Wildlife Services' annual killing of tens of thousands of wolves, coyotes, bears, bobcats, cougars and other animals unconscionable, it's also ineffective," said Michael Robinson of the Center for Biological Diversity. "Our government should ground the aerial snipers, pull the poisons and remove the steel leghold traps in response to these findings."

The unexpected finding that carnivore killings can increase depredations is likely based on disruption of the predators' social dynamics, the organization stated. By removing dominant animals that maintain

Studies done in North America and Europe concluded that killing predators, such as wolves, does not reduce livestock losses.

large territories, these killings release subadult animals that are less-skilled hunters and thus more likely to target domestic animals.

The new review, "Predator Control Should Not Be a Shot in the Dark"—published in one of the world's top scientific journals, *Frontiers of Ecology and the Environment*—evaluated the methods in 24 previous studies of responses to predation on livestock and catalogued them according to their adherence to the scientific method.

The review found few studies that met accepted standards for scientific evidence. Half of the evaluated studies—conducted in North America and Europe—did not follow an experimental design that included control (non-manipulated) herds of livestock and other standard scientific safeguards to exclude the effects of bias in sampling, treatment, measurement or reporting. However, the review found 12 studies that were conducted according to the scientific method. Most of the tests of lethal methods showed no effect or unexpected increases in livestock deaths. Nonlethal methods were found to be safer and more effective.

## CURRENT E-EDITION

Two of the studies that used sound methods found that nonlethal measures, specifically guard dogs and fladry (ribbons attached to fences to scare predators away from lambing pastures), were effective at deterring livestock depredations.

The study was conducted by Adrian Treves of the University of Wisconsin, Miha Krofel of the University of Ljubljana in Slovenia and Jeanine McManus of the University of Witwatersrand in South Africa.
